

Dependency, configuration and event-order investigation

Purpose

Investigate overlapping dependency errors, configuration changes or clock/order anomalies across payment stages. Correlation identifies a hypothesis, not a root cause. A configuration rollback is not a reversal of a payment outcome.

The Platform Owner supplies effective change/dependency observations; Security Owner handles access/credential failures. Stage owners retain authority over their payment confirmations. This guide adds no deployable service.

Document control	Value
Key / version	RB-110 / 1.0.0

Compare scope, version and time

Investigation sequence

Start with E01 service, exact window, status and counts. Keep unrelated services, routes or regions separate. Do not derive a failure rate without an observed denominator or convert technical error counts to payment outcomes.

Request E10 approved configuration identity, effective interval, change history and applicable route/deadline/retry rule. Compare only changes effective for the affected source/window. A later configuration cannot explain an earlier request without additional evidence. A change near an error is not sufficient causal proof.

Request E11 bounded health, connectivity, access and clock observations. Preserve source event versus received/collected times. Compare sequence within one stream; cross-source timestamps with unknown offsets do not establish transition order. Check a comparable unaffected scope if available, documenting its differences rather than declaring a universal healthy control.

Competing hypotheses

Observation	Distinguishing check
Errors follow an effective change	Matching scope/version and affected mechanism versus coincident dependency failure
Apparent late or reversed event	Source sequence, event time and clock uncertainty versus transport arrival order
Access failure	Bounded permission/context metadata versus expired or incorrect credential hypothesis
Multiple stage errors	Shared dependency scope versus unrelated failures with different windows

Missing configuration or health snapshots leave the explanation unresolved. Do not request or log secrets, weaken TLS/access checks or infer a card condition from technical dependency errors.

Recovery requires a separate change record

Conditional advice

Recommend owner review of the specific dependency/configuration only when the observed comparison supports that direction. Name the evidence needed to distinguish alternative causes. Any controlled change must specify owner, authorization, effective version, affected scope, validation window and rollback plan under PL-105. The copilot never rotates keys, adjusts clocks or modifies routes.

For event-order issues, preserve source history and have the owner review projection logic. Rewriting event timestamps to make a timeline consistent is prohibited. A clock correction affects future interpretation; it does not silently change past confirmation evidence.

Validate and escalate

After an authorized change, compare like-for-like observation windows and source versions. Error reduction is bounded operational evidence, not proof of all prior payment outcomes. Rollback must identify the previously effective configuration; separate stage confirmations remain necessary.

Current MCP exposes E01 only. E10/E11 are future requirements, and unavailable health/configuration sources must remain explicit. Retain conflicting data, owner requests and human checkpoints; degraded/empty reports keep Q6 LOW/null fields.
